Phu Nguyen

For this lab I went through the notebook in order and ran the code myself so I could see what each part was doing. I loaded the Titanic data, then trained a Linear Regression model to predict Fare using Age and Pclass, and checked the error with mean squared error. After that I trained a Logistic Regression model to predict Survived using Age, Pclass, and Sex, and checked it with accuracy.

For the two tasks and the knowledge check questions, I got help from Claude. After that I ran the code, printed the .coef_ and looked at the numbers myself, and wrote the answers so they made sense to me.

This lab made me see the difference between regression and classification, and why each one needs a different metric. When I finished, I uploaded it to my GitHub repo and submitted it.

Cyndy Ndong

For my contribution to Lab 06 completed all technical, analytical, and documentation tasks required for the assignment from start to finish. First, I set up the Google Colab environment, loaded the Titanic dataset, and performed essential data cleaning by dropping null values in Age and mapping Sex to binary numeric values. Second, I defined the feature matrices and target variables, using train_test_split to prepare the training and test sets for both regression and classification pipelines.

Third, I imported, trained, and evaluated the Linear Regression model using Mean Squared Error

to measure continuous fare predictions. Fourth, I imported, trained, and evaluated the Logistic Regression model using Accuracy Score to measure passenger survival prediction. Fifth, I

systematically debugged syntax errors, missing package imports, and variable scope errors to ensure every cell executed sequentially without errors. Sixth, I answered all theoretical Knowledge Check questions within the notebook markdown cells to explain model evaluation metrics and coefficient interpretation. Finally, I formatted and compiled all documentation to ensure the deliverables met the required repository naming conventions for submission.
